

important point

- > When we create new file and push into staging area then index is created for that file based on its contents.
- > If already existing file is modified then its index number also get modified
- > If two files content are same then they have same index number. index number is also called hashcode or SHA-1 key.
- > Index number or hashcode has 40 characters.
- > If want to view an index of any file then use below command
git ls-files -s file_name
- > If we want to view index of all files then use below command
git ls-files -s

-> Practical Example:

```
Dell@DESKTOP-1VT9LL4 MINGW64 /e/DevOps/git-practice (feature-002)
$ git ls-files -s T1.txt                      To view index of particular file
hint: core.useBuiltinFSMonitor=true is deprecated;please set core.fsmon
instead
100644 5ab2f8a4323abafb10abb68657d9d39f1a775057 0      T1.txt

Dell@DESKTOP-1VT9LL4 MINGW64 /e/DevOps/git-practice (feature-002)
$ git ls-files -s                      To view index of all files
hint: core.useBuiltinFSMonitor=true is deprecated;please set core.fsmon
instead

Creating a branch on github(Central Repository) and cloneing it.

- > When a task is assigned to you then we need to follow certain steps to complete the task.
- > Check the task details in ticketing tool(Jira)
i.e before starting work on the task first go through all the details which are mentioned in the ticketing tool.
- > Suppose there is code changes or database changes,some configuration settings.
 1. First find its code repository on github
 2. Find latest branch/release branch of this repository.
i.e release branch means-the branch which holds current month development changes.
go on that branch - create your branch like feature branch,bug-fix-branch

while creating a branch we need to follow nameing convention like
feature-story_number
or
feature-jira_number
or
bugfix-issue_number.

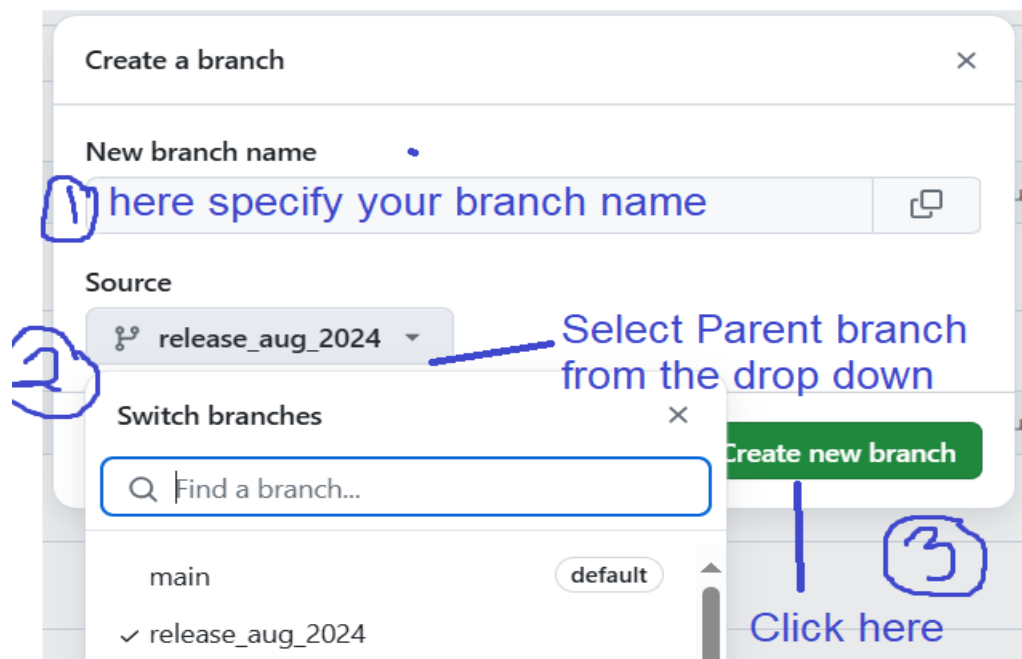

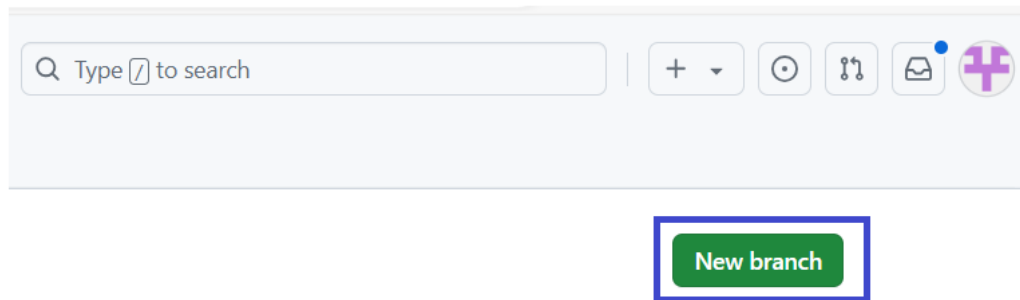

For practice purpose follow the below nameing convention
feature-month_name-your_names_initial_letters

Practical implementation of creating a branch and cloneing it on local system

1. login to github account
2. Go repository(TASKS)

The screenshot shows the GitHub interface for the repository 'RRDTNP / TASKS'. The URL in the browser is 'https://github.com/RRDTNP/TASKS'. The repository name 'TASKS' is highlighted with a blue box and labeled 'Repository name'. The organization name 'RRDTNP' is labeled 'organization name'. The '25 Branches' link is highlighted with a blue box and labeled 'Click on the Branches'. The 'main' branch is selected. The 'README.md' file is visible in the file list.

3. on right-top corner we have "New Branch" Button click on that button

How to clone created brach on local system?

- > Go to work folder (Devops)
- > Right click one gitbash

-> Type below command to clone a branch

Syntax

`git clone -b branch_name repository_url`

Example:

`git clone -b feature-aug-ddh https://github.com/RRDTNP/TASKS.git`

your branch name

Repository URL will remain same

One branch is cloned.close your git bash and go to your local repository(TASK)

Flow- Push the changes from
local repository to central repository
branch which you have cloned
